FINAL REPORT

Introduction

This project focuses on improving incident management in the ServiceNow platform by enforcing mandatory fields using UI Policies and managing configuration changes through Update Sets. In many organizations, incomplete incident records can lead to confusion, delays in issue resolution, and inefficient workflow management. The purpose of this project is to ensure that important information is always captured before an incident progresses to the next stage.

Project Objective

The main objective of this project is to demonstrate how ServiceNow configuration tools can be used to enforce business rules and improve data accuracy without writing complex scripts.

The specific objectives include:

- Enforcing mandatory fields in incident forms
- Using UI Policies to control field behavior dynamically
- Capturing configuration changes using Update Sets
- Migrating configurations between ServiceNow instances

Methodology

The project was implemented using the ServiceNow platform by following a structured development process.

1. **Requirement Analysis**
   The problem of missing priority information in incident records was identified.
2. **Project Design**
   A UI Policy was designed to make the Priority field mandatory when the incident state changes to "In Progress".
3. **Implementation**
   The UI Policy and UI Policy Action were configured within the ServiceNow system. All changes were captured using an Update Set.
4. **Migration**
   The Update Set was exported as an XML file and imported into another ServiceNow instance.

5. **Testing**
   Incident records were tested to verify that the Priority field becomes mandatory when the state changes to "In Progress".

Tools and Technologies Used

The following tools and technologies were used in this project:

- ServiceNow Platform
- UI Policies
- UI Policy Actions
- Update Sets
- Web Browser (Google Chrome or Microsoft Edge)

Results

The project successfully demonstrated how UI Policies can be used to enforce mandatory fields dynamically within the ServiceNow platform. When the incident state is set to "In Progress", the system automatically requires the user to enter a priority value before saving the record.

The configuration changes were successfully captured and migrated using Update Sets, ensuring that the implementation can be replicated across different ServiceNow instances.

Advantages of the Project

- Improves data completeness in incident records
- Enhances incident prioritization
- Reduces manual verification
- Supports configuration migration across instances
- Requires no scripting for implementation

Conclusion

The project demonstrates how ServiceNow configuration tools can be effectively used to enforce business rules and improve system efficiency. By implementing UI Policies and using Update Sets for migration, organizations can maintain accurate incident data and ensure consistent system configurations across environments.
